## Abstract

*Promastobranchnus* Gallardo, 1968 is a small genus in the polychaete family Capitellidae, and the available records are largely reported from the Indo-West Pacific region. Although Gallardo (1968) and Green (2002) noted that *Promastobranchnus* species had intraspecific variation in the number of thoracic chaetigers when they described the two previously known species, this variation has not been corroborated using molecular evidence. In this study, a new *Promastobranchnus* species, *Promastobranchnus variabilis* sp. nov., is described based on 29 specimens collected from the Beibu Gulf, South China Sea. The new species is mainly characterized by having a tessellated epithelium in the anterior thorax, nine teeth in three rows above the main fang in the abdominal hooks, four pairs of genital pores located on the intersegmental grooves between chaetigers 9 and 13, and its unique methyl green staining pattern. Comparisons of multiple gene markers (16S, 18S, 28S, and H3) revealed no genetic divergence ( $K2P < 0.003$ ) among these type specimens with 9–13 thoracic chaetigers. In other words, the new species exhibited morphological variability in the number of thoracic chaetigers during ontogeny, and this character was unsuitable to differentiate *Promastobranchnus* species as the ranges overlap among *Promastobranchnus* species. This is the third *Promastobranchnus* species known in the world, and it is now recorded along the Fujian coast.

**Key words:** Mitochondrial markers, nuclear markers, polychaete, South China Sea, taxonomy

## Introduction

Members of the polychaete family Capitellidae are commonly encountered components of marine infaunal communities and are especially abundant in organically enriched sediments (Blake 2000; Magalhães and Blake 2020). To date, the family contains more than 200 described species in 41 genera (Read and Fauchald 2023). Of these genera, *Promastobranchnus* Gallardo, 1968 is a small genus with only two described species worldwide. *Promastobranchnus* is a unique genus, and it can be readily distinguished from other capitellid genera in bearing relatively long capillary chaetae in the notopodia throughout the abdomen, as

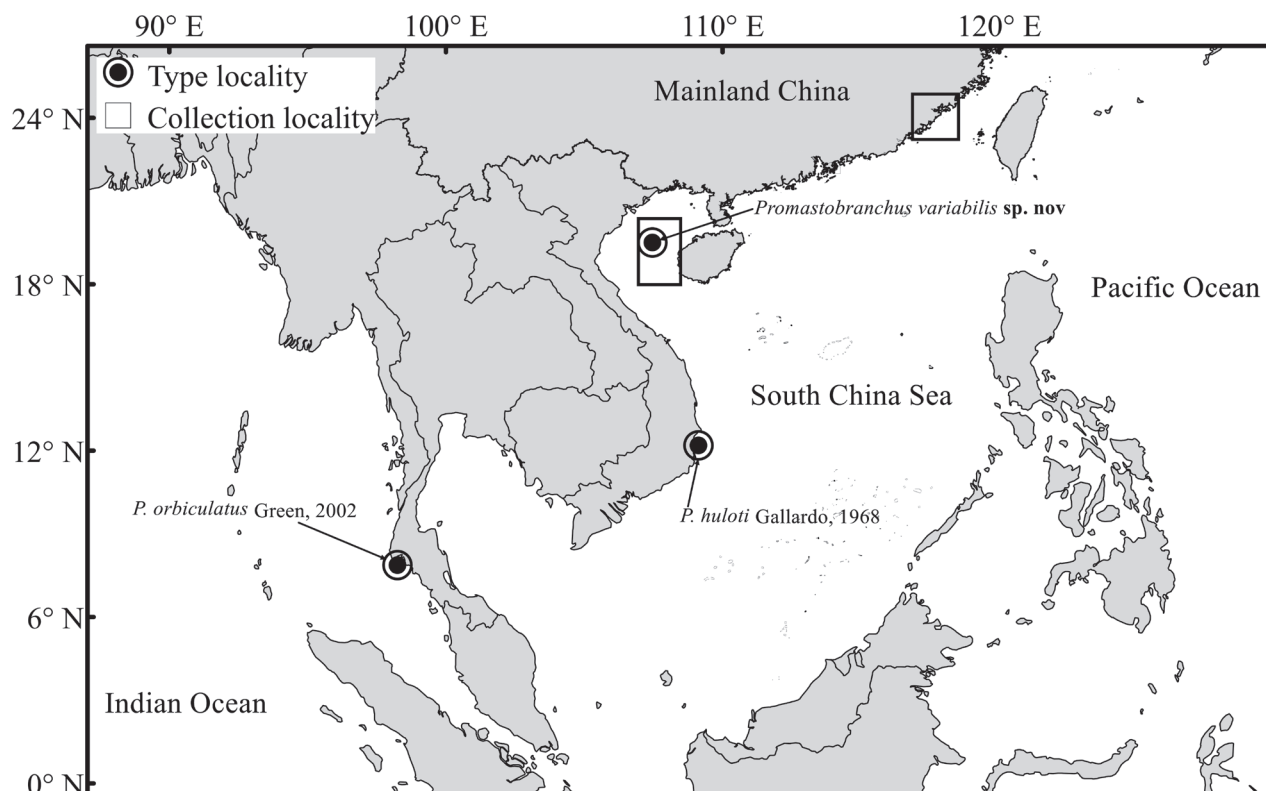

well as the relatively long prechaetal region (Green 2002; Magalhães and Blake 2020). According to the available records, *Promastobranchnus* appears to be endemic to the Indo-West Pacific region. Type localities of the two known species are located in this region: *Promastobranchnus huloti* Gallardo, 1968 from near-shore waters off southern Vietnam and *Promastobranchnus orbiculatus* Green, 2002 from the Thailand part of the Andaman Sea. Other records of *Promastobranchnus* were also reported from this region, such as Natuna Islands (Al-Hakim and Glasby 2004), Sulawesi Island (Lin et al. 2018), and northern Australian (data from Ocean Biodiversity Information System, <https://www.obis.org>).

The number of thoracic chaetigers is an important diagnostic character used to differentiate capitellid genera (Blake 2000). The majority of species in Capitellidae bear a fixed number of thoracic chaetigers without intraspecific variation. Species of *Notomastus* Sars, 1851 have 11 thoracic chaetigers while those of *Mediomastus* Hartman, 1944 have 10. However, *Leiocapitella* Hartman, 1947 has interspecific but not intraspecific variation in the number of thoracic chaetigers (12–16). More specially, *Promastobranchnus*, together with *Scyphoproctus* Gravier, 1904, have been reported to have intraspecific variation in the number of thoracic chaetigers. *Promastobranchnus huloti* was reported to have 12 or 13 thoracic chaetigers (Gallardo 1968). Green (2002) described *P. orbiculatus* based on specimens with 9–12 thoracic chaetigers with capillary chaetae in both rami, and these specimens possessed an identical dental formula of hooks. Nevertheless, morphological variability had not been corroborated using molecular evidence until this study. In recent samplings, 29 *Promastobranchnus* specimens with 9–13 thoracic chaetigers were collected from the Beibu Gulf, South China Sea. Using multiple gene markers of the newly collected specimens, we attempted to verify whether these specimens belong to an identical species or whether there was hidden diversity. The results indicate that these specimens belong to an identical species without genetic divergence and that the species is new to science, *P. variabilis* sp. nov. The new species bears a variable number of thoracic chaetigers (9–13), a character not useful for differentiation among *Promastobranchnus* species. This is the third species in the genus *Promastobranchnus* worldwide. The new species also occurs along the Fujian coast, approximately 1100 km northeast of its type locality, based on genetic comparison. The phylogenetic position of *Promastobranchnus* and its sister genera within the family will be evaluated when molecular data of its closest related genera (e.g., *Scyphoproctus*) are available.

## Materials and methods

### Field sampling

Sampling was conducted at two localities (Beibu Gulf, South China Sea and coastal waters of Fujian Province) along south Chinese coast during 2020–2022". The text would be clearer. (Fig. 1). Sediment samples were collected using a grab sampler and subsequently washed through a 0.5 mm sieve in the field. The specimens retained in the sieve were directly preserved in 90% ethanol.

**Figure 1.** Type localities of the three *Promastobranchnus* species (circles) and two sampling localities (squares) included in this study

### Morphological observation

In the lab, specimens of the target species were picked out of the samples and examined under a Leica MZ95 stereoscope. Detailed information on the examined specimens is shown in Table 1. Light photographs were taken under a Leica M205A stereoscope equipped with a DFC 550 digital camera. The structure of abdominal hooks was observed under a Leica DM6B microscope using oil emersion ( $\times 100$ ). Observations were performed on a scanning electron microscope (TESCAN MIRA) at the Third Institute of Oceanography, and the methyl green staining pattern (MGSP) was used to identify the distribution of glandular areas, both as delineated by Lin et al. (2019). The type material and additional material examined in this study were deposited at the Third Institute of Oceanography, Ministry of Natural Resources, Xiamen, China (TIO, MNR).

### DNA extraction, PCR amplification, and sequencing

The total genomic DNA was extracted from organisms using Transgen Micro Genomic DNA EE 181 Kit (Transgen, Beijing, China) following the protocol provided by the manufacturer. Polymerase chain reactions (PCRs) were conducted to amplify partial sequences of mitochondrial (16S) and nuclear (18S, 28S, H3) genes using primer sets and thermal cycling conditions as shown in Table 2. The 50- $\mu$ L PCR mixtures contained 25  $\mu$ L of 2X PCR Mix (Vazyme, Nanjing, China), 2  $\mu$ L of DNA template, 2  $\mu$ L of each primer, and 19  $\mu$ L of deionized water. Then, the 5- $\mu$ L PCR products were subsequently checked using 1% agarose

gel electrophoresis. Sequencing of the successful products was performed in both directions at the Sangon Co. (Shanghai, China) with an ABI 3730XL DNA analyzer (Applied Biosystems). Both forward and reverse strands of sequences were manually assembled into a consensus sequence using DNAMAN software (Lynnon Biosoft, Quebec, Canada).

### Data analysis

Alignments of each gene were performed using MAFFT (Kato et al. 2002) with default settings. The aligned and trimmed sequences were used as data sets to generate the mean genetic distances within and between the two sampling sites (Beibu Gulf and the Fujian coast) based on the Kimura's 2-parameter (K2P) model (Kimura 1980) implemented in MEGA X (Kumar et al. 2018).

## Taxonomy

### Family Capitellidae Grube, 1862

### Genus *Promastobranchnus* Gallardo, 1968

*Promastobranchnus* Gallardo, 1968: 121; Green 2002: 324; Magalhães and Blake 2020: 391.

**Type species.** *Promastobranchnus huloti* Gallardo, 1968.

**Diagnosis (after Magalhães and Blake 2020).** Prostomium rounded, without palpode; eyespots present in multiple spots. Peristomium clearly distinct from prostomium. First chaetiger biramous. Nine to thirteen thoracic chaetigers. Thoracic chaetigers with only capillaries in both rami. Thorax clearly demarcated from abdomen. All abdominal segments transitional with notopodial capillaries and neuropodial hooded hooks. Branchiae absent. Genital pores, up to four pairs starting from chaetigers 9/10 or 10/11. Lateral organs present in thorax and abdomen. Pygidium adorned with a pair of ventral cirri.

***Promastobranchnus variabilis* sp. nov.**

Figs 2A–F, 3A–K, 4A–G

**Material examined. Holotype:** TIO-BTS-Poly139, complete, Beibu Gulf, sta. S31 (19.65°N, 107.70°E), 65 m depth, coll. Jun-Hui Lin, 23 May 2021. **Paratypes:** TIO-BTS-Poly140 • 1 spec., incomplete, same information as holotype. TIO-BTS-Poly141 • 4 specs, all incomplete, Beibu Gulf, sta. S42 (19.25°N, 108.10°E), 59 m depth, coll. Jun-Hui Lin, 24 May 2021. TIO-BTS-Poly142 • 3 specs, TIO-BTS-Poly143 • 5 specs and TIO-BTS-Poly144 • 6 specs, all incomplete, Beibu Gulf, sta. S44 (19.25°N, 108.50°E), 36 m depth, coll. Jun-Hui Lin, 24 May 2021. TIO-BTS-Poly145 • 4 specs, TIO-BTS-Poly146 • 3 specs and TIO-BTS-Poly147 • 1 spec., all incomplete, Beibu Gulf, sta. S51 (18.85°N, 108.50°E), 15 m depth, coll. Jun-Hui Lin, 26 May 2021. TIO-BTS-Poly148 • 1 spec., incomplete (posterior fragment with pygidium), Beibu Gulf, sta. S14 (20.456°N, 108.50°E), 55 m depth, coll. You-Ling Ye, 27 Nov 2022.

**Description.** Holotype complete, but broken into two fragments. Anterior fragment heavily coiled (Fig. 3A), measuring 35.99 mm long by 1.27 mm wide (at chaetiger 15) for 71 chaetigers; posterior fragment measuring 10.69 mm long for 35 chaetigers. Paratypes incomplete, ranging from 2.68–19.12 mm long, 0.45–1.52 mm wide for 15–34 chaetigers. Body nearly cylindrical, widest in anterior abdomen. Color in alcohol tan (Fig. 3C). Nuchal organ not observed.

Prostomium rounded without palpode, partially concealed by peristomium (Figs 2A, B, 3A–C); eyespots present on lateral sides of prostomium when dissected (obviously seen in some specimens as shown in Fig. 3D). Proboscis retracted in holotype (Fig. 3A–C), with numerous minute papillae. Peristomium achaetous, wider than long, longer than chaetiger 1 (Figs 2A, 3A). Intersegmental groove distinct between peristomium and chaetiger 1 (Figs 2A, B, 3B, 4A, B).

Thorax with 11 chaetigers (Fig. 2A) in holotype, first chaetiger biramous (Figs 2A, B, 3B). Thoracic segments bi-annulated, wider than long, with epithelium areolated from peristomium to chaetiger 7, faintly areolated on chaetiger 8, and smooth on following segments (Figs 2A, B, 3B). Chaetigers 1–11 with only capillaries in both rami (Figs 2A, 3A), 18–30 per fascicle in notopodia and 20–30 per fascicle in neuropodia. Notopodia inserted dorso-laterally, and neuropodia ventro-lateral. Chaetal fascicles inserted just near midline of thoracic segments (Figs 2A–C, 3B). Lateral organs located between noto- and neuropodia at intrasegmental grooves, closer to notopodia in thorax and anterior abdomen, as small pores (Figs 2A, 3B). Genital pores present on intersegmental grooves of between chaetigers 9/10, 10/11, 11/12, and 12/13 in holotype.

Transition between thorax and abdomen marked by chaetal change (Figs 2A, C, 3E, 4C, D). Abdominal segments longer and wider than posterior thoracic chaetigers in anterior abdomen (Fig. 3A, E), tapering gradually towards pygidium (Fig. 3G, H). Parapodial lobes reduced in anterior abdomen (Fig. 3A, E), well separated. Neuropodial tori pad protruded above body surface from middle-posterior abdomen (Fig. 3H). Abdominal chaetigers transitional with notopodial capillaries and neuropodial hooks throughout (Figs 2C–E, 3G, H), with 15–20 notopodial capillaries and 60–70 neuropodial hooks in anterior abdomen, decreasing to 8–10 capillaries and 30–40 hooks in posterior end. In anterior abdomen, notopodial lobes located dorso-laterally and neuropodial lobes

**Figure 2.** *Promastobranchnus variabilis* sp. nov., holotype **A** thorax and anterior abdomen, lateral view **B** anterior end, ventro-lateral view **C** chaetigers 9–16, lateral view **D** middle-posterior abdomen, dorso-lateral view **E** posterior end with anal cirri, ventral view **F** abdominal hooded hook of chaetiger 70. ventro-lateral (Figs 2C, 3E). From middle abdomen, notopodial lobes lateral and neuropodial lobes ventral (Figs 2D, E, 3A, H). Chaetal fascicles positioned posterior to midsegment in anterior abdomen (Fig. 3E), and near posterior edge of segment toward the pygidium (Fig. 3F). In the far posterior abdomen, neuropodial lobes close to each other with a small gap (Figs 2E, 3H, 4E).

Hooded hooks with angled node, evident constriction, developed shoulder, posterior shaft longer than anterior one, attenuated to terminal end (Figs 2F, 3J).

**Figure 3.** Light micrographs of *Promastobranchnus variabilis* sp. nov., holotype (A–C, E–K) and paratype (D) A anterior fragment showing MGSP B anterior thorax with areolated epithelium, ventro-lateral view C anterior end, lateral view D anterior end showing eyespots, dorsal view E transition between thorax and abdomen, lateral view F middle-posterior abdomen, dorso-lateral view G posterior abdomen, dorsal view H posterior abdomen, ventral view I posterior end, end view (anal cirri have been outlined with black lines) J hooded hooks at chaetiger 70, lateral view K hooded hooks, frontal view. Abbreviations: cc, capillary chaetae; ch, chaetiger; es, eyespot; hh, hooded hook; lo, lateral organ; neu, neuropodia; no, notopodia; per, peristomium; pro, prostomium. Scale bars: 1 mm (A, B, E–H); 0.5 mm (C); 0.2 mm (D, I); 50 μm (J); 10 μm (K).

**Figure 4.** SEM photographs of *Promastobranchnus variabilis* sp. nov., paratype (TIO-BTS-Poly144) **A** anterior 13 chaetigers **B** anterior end, ventro-lateral view **C** transition between thorax and abdomen, lateral view **D** genital pore on between chaetigers 11/12, lateral view **E** posterior end showing neuropodia, ventral view **F** abdominal hooks at chaetiger 16 **G** ultrastructure of hooks. Abbreviations: cc, capillary chaetae; gp, genital pore; hh, hooded hook; mf, main fang; neu, neuropodia; per, peristomium. Scale bars: 200  $\mu\text{m}$  (**A–E**); 20  $\mu\text{m}$  (**F**); 5  $\mu\text{m}$  (**G**).

Hood with dentate distal edge (Figs 3K, 4F, G), slightly longer than wide (Figs 2F, 3J). Hooded hooks (Fig. 4G) with three rows of teeth above main fang: four teeth in basal row, three teeth in middle row, two smaller teeth in apical row. Main fang subtriangular, longer than wide.

No branchiae observed in abdomen. Pygidium with two digitate anal cirri on ventral side (Figs 2E, 3I).

Methyl green staining pattern (Figs 2A, C, D, 3A, E–H). Body stained with pale green and small dark spots of stain scattered from peristomium to prechaetal part of chaetiger 9. Body stained dark blue in dorsum of from postchaetal part of chaetiger 9 to chaetiger 20, excluding intra- and intersegmental grooves and parapodial lobes, extending to dorsal sides of neuropodia. Four pairs of genital

pores (between chaetigers 9–13) stained dark blue in holotype. From chaetiger 21, each segment has a dorsal transverse band of dark stain located on between notopodial tori, as well as stain around noto- and neuropodial tori. In far posterior abdomen, dorsum stained dark blue, reaching dorsal side of neuropodial tori, interrupted by intersegmental groove.

**Sequences.** The amplification of the COI gene failed for all specimens. In total, 11 partial sequences of 16S, 14 partial sequences of 18S, 13 partial sequences of 28S, and 14 partial sequences of H3 were successfully obtained from 14 specimens with 9–13 thoracic chaetigers (Table 1). There is no genetic divergence (mean K2P < 0.003, with up to two base changes) among specimens from the type locality, and between the type locality and off the Fujian coast (Table 3).

**Distribution.** Currently known from Beibu Gulf (South China Sea) and off the Fujian coast.

**Ecology.** The new species inhabits shallow-sea (10–65 m) sediments characterized by mud, muddy sand, or sandy mud with shell fragments.

**Etymology.** The specific name was derived from its variable number of thoracic chaetigers (9–13) during ontogeny.

**Variation.** The majority (79%) of the type specimens possess 10 or 11 thoracic chaetigers with capillaries in both rami. Larger specimens (>1.0 mm wide) have 11–13 chaetigers with only capillaries. Areolated epithelium was clearly seen in large specimens, while obscured in the small ones. The holotype stained dark blue on four pairs of genital pores (between chaetigers 9–13), whereas some specimens have blue stain on two pairs of genital pores (on chaetigers 9–11).

**Remarks.** Among the type specimens included in this study, the holotype is the only complete one. It has more discernable morphological characters than the others, such as the form of the thoracic epithelium and genital pores and, although it was not the largest specimen, it was considered the best for the holotype. Judging from its body size (body width >1 mm), it should be a mature specimen.

The new species shares a few morphological features with the two previously known species. They all possess a rounded prostomium without a palpode, eyespots on the lateral sides of the prostomium, four pairs of genital pores on the anterior body, reduced parapodia in the anterior abdomen, two anal cirri on the ventral side of the pygidium, and a variable number of chaetigers with capillaries in both rami. Despite the highly similar body appearance, *Promastobranchnus variabilis* sp. nov. differs from *P. huloti* mainly in the dental formula of hooks and neuropodia in the preanal region, as shown in Table 4. The hooks of the new species have nine teeth in three rows (2+3+4), instead of four teeth in a single row as in *P. huloti*. The number of neuropodial hooks in the preanal region is much higher in *Promastobranchnus variabilis* sp. nov. (30–40 hooks) than in *P. huloti* (2 or 3 hooks). *Promastobranchnus variabilis* sp. nov. can be also distinguished from *P. orbiculatus* mainly by the dental formula of hooks and the position of the genital pores. The former species has nine teeth while the latter has six teeth (2+4). Besides, the new species has four genital pores present on the intersegmental grooves of chaetigers 9–13, instead of those of chaetigers 10–14 as in *P. orbiculatus*. As for MGSP, the new species has a single dark transverse band per segment located on notopodia from chaetiger 21, which was absent in the other two species. Moreover, the

**Table 4.** Comparison with the known *Promastobranchnus* species around the world. Abbreviations: No: notopodia; Neu: neuropodia.

Species	<i>P. huloti</i>	<i>P. orbiculatus</i>	<i>P. variabilis</i> sp. nov.
Prostomium	rounded without palpode	rounded without palpode	rounded without palpode
Eyespots	present	present	present
Thoracic epithelium	unknown	smooth	areolated up to chaetiger 8
Number of thoracic chaetigers	12–13	9–12	9–13
Branchiae	absent	absent	absent
Dental formula of abdominal hooks	4 in a single row	6 in two rows (2+4)	9 in three rows (2+3+4)
Location of genital pores	Chaetigers 9–13	Chaetigers 10–14	Chaetigers 9–13
Neuropodia in posterior abdomen	unknown	reduced	protruded above surface
Number of chaetae in preanal region	No: a few capillaries; Neu: 2–3 hooks	No: 6–8 capillaries; Neu: 30–45 hooks	No: 8–10 capillaries; Neu: 30–40 hooks
MGSP	a dorsal band of stain on chaetiger 27	dark stain around 4 pairs of genital pores	dark stain on 4 pairs of genital pores, and a dark dorsal transverse band from chaetiger 21
Habitat	8–43 m; mud, sandy mud, muddy sand, coarse sand	19–59 m; mud, sandy mud, muddy sand, sand	10–65 m; mud, sand, muddy sand with shell fragment
Type locality	South Vietnam, South China Sea	Andaman Sea, Thailand	Beibu Gulf, South China Sea
References	Gallardo 1968; Green 2002	Green 2002	This study

new species bears an areolated epithelium from the peristomium to chaetiger 8 and protruded neuropodial tori in the posterior abdomen, which are not observed in its congeners.

## Discussion

In this study, there is no genetic divergence among type specimens of *Promastobranchnus variabilis* sp. nov. with a variable number of thoracic chaetigers (9–13) using multiple gene markers, which confirmed the examined specimens belong to *Promastobranchnus variabilis* sp. nov. In other words, the new species does exhibit intraspecific variability in the number of thoracic chaetigers with capillaries. The number of thoracic chaetigers of the new species may be size dependent, and smaller individuals bear fewer thoracic chaetigers. The new species, together with the two previously known *Promastobranchnus* species, possesses a variable number of thoracic chae-

tigers, indicating that the number of thoracic chaetigers is inappropriate to identify *Promastobranchnus* species, as this character overlaps between *Promastobranchnus* species. In contrast, diagnostic characters such as the dental formula of abdominal hooks, the number and location of genital pores, and the MGSP are helpful in identification, as suggested by Green (2002). The use of mature specimens is recommended for identification, as several diagnostic characters may be obscured in immature ones, such as thoracic epithelium and genital pores. In this study, we also observe the presence of an areolated epithelium in the anterior thorax and protruded neuropodial tori pad in the middle-posterior abdomen, which may be helpful in differentiating *Promastobranchnus* species.

Based on genetic comparisons, the new species has a broad geographical distribution, and ranges from its type locality northeastward to the Fujian coast, which is approximately 1100 km away from the type locality. Green (2002) noted that *Promastobranchnus* resembles *Scyphoproctus* in that both genera had relatively long capillary chaetae and a relatively long achaetous segment. In addition, these genera also share a broadly rounded prostomium without a palpode and a variable number of thoracic chaetigers. Currently, the lack of molecular data of closely related genera, such as *Scyphoproctus*, hinders evaluation of the phylogenetic relationship of *Promastobranchnus*.

## Acknowledgements

We are grateful to the captain and crew of the R/V Haijian 203 for help in collecting the sediment samples during the cruises organized by the Third Institute of Oceanography (Xiamen, China). We appreciate Mr Weiming Kuang for his assistance in SEM observations. We also thank Dr Chris Glasby and Dr Wagner Mahalgães for their invaluable comments on the manuscript.

## Additional information

### Conflict of interest

The authors have declared that no competing interests exist.

### Ethical statement

No ethical statement was reported.

### Funding

This study was financially supported by the Asian Cooperation Fund Project “Study on Typical Bay Ecological Protection and Management Demonstration” and the Natural Science Foundation of Xiamen city (3502Z20227249).

### Author contributions

Lin J-H and Lin H-S designed the study; Lin J-H and Mou J-F conducted morphological examination and molecular analyses; Lin J-H and Lin H-S wrote the first draft. All authors read, revised and approved the submission.

### Data availability

All of the data that support the findings of this study are available in the main text.
