CAPÍTULO 1

EL PROBLEMA DEL AGUA

1.1 INTRODUCCIÓN.

La expansión acelerada que han tenido los desarrollos humanos en los últimos años en el mundo ha provocado que temas como del agua potable, el cambio climático, las energías renovables, la huella hídrica y el desarrollo sustentable, entre otros; sean de gran interés para la elaboración de varias investigaciones que tienen como fin común mitigar en cierta medida el impacto que se le ha generado al planeta y desacelerar el deterioro del mismo.

Actualmente, la Tierra es el lugar donde habita una gran diversidad de seres vivos, incluidos nosotros los seres humanos, cuyo número está en constante crecimiento. Las afectaciones de este incremento demográfico en el mundo son muchas, por ejemplo: el planeta tiene que abastecer primordialmente de alimento y “agua” a cada uno de los seres vivos, con los mismos recursos que se tienen actualmente; ya que, como es bien sabido, “la materia no se crea ni se destruye solo se transforma”. En palabras más crudas, todo lo que uno consume se transforma, por lo general, en desecho y ese desecho es o serán los nuevos

recursos para las generaciones venideras a este planeta, si no se ejerce un control sobre los recursos disponibles actualmente.

Ahora bien, centrándose en el tema de esta investigación, cabe mencionar que el recurso más indispensable para que la vida continúe es el agua. Este elemento, indirectamente, es uno de los tesoros más preciados para el desarrollo de una población, ya que todos los seres vivos requieren de una dotación diaria de este elemento, para realizar sus actividades cotidianas sin ningún inconveniente.

Generalmente, la población que habita en las ciudades no tiene una idea clara del problema del agua, debido a que todos los satisfactores necesarios para sobrevivir, incluidos entre ellos el agua potable, llegan directamente a sus hogares, sin saber todo el camino que recorre una gota desde su origen hasta el grifo de su hogar, por mencionar un ejemplo. Por tal motivo, cuando el problema llega a tener un grado de afectación en la población urbana se requieren medidas extremas para llegar a controlar la situación.

No se puede seguir ignorando el hecho de que cada día nos enfrentamos a una progresiva reducción de la dotación de las principales fuentes de agua dulce que es utilizada para abastecer a las ciudades y no conviene esperar a que las autoridades resuelvan el problema de abastecimiento de manera unilateral, pues éste es un problema que rebasa las capacidades de una sola instancia (Adler, et al., 2008).

1.2 EL AGUA EN EL MUNDO.

Al indagar el origen del agua que sale del grifo, una respuesta general sería que de las fuentes de abastecimiento; ya sea de cuerpos de agua superficiales o subterráneos; pero sea cual sea la fuente de abastecimiento, surgirían las siguientes interrogantes ¿Es suficiente la cantidad de agua disponible actualmente?, ¿Es ésta de buena calidad para el consumo humano?

Para responder estos cuestionamientos, se comenzará a hablar sobre la distribución de agua dulce en el planeta y el ciclo del agua para posteriormente atender el problema que se tiene actualmente por el agua.

Es bien sabido que un 70% de la superficie de la Tierra es agua y que tan sólo un 30% es tierra firme. De ese 70%, el 96.5% es agua salada de mares y océanos. El restante 3.5% es agua dulce, pero casi toda está congelada en los polos y en los glaciares. Del agua dulce, un 68.7% es agua congelada, un 30.1% es subterránea y en los ríos y los lagos hay sólo un 0.3%. En la Tabla 1 se presenta un resumen de los valores estimados en cuanto a la disponibilidad del agua.

Tabla 1 Estimación de la distribución global de agua (Hernández & Villa Cisneros , 2013)

Fuente de Agua	Volumen de Agua en Km^3	Porcentaje de Agua Dulce	Porcentaje del Agua Total
Océanos y mares	1,338,000,000	--	96.5
Casquetes y glaciares polares	24,064,000	68.7	1.74
Agua subterránea salada	12,870,000	--	0.93
Agua subterránea dulce	10,530,000	30.1	0.76
Humedad del suelo	16,500	0.05	0.001
Glaciares continentales	300,000	0.86	0.022
Lagos de agua dulce	91,000	0.26	0.007
Lagos de agua salada	85,400	--	0.006
Atmósfera	12,900	0.04	0.001
Embalses	11,470	0.03	0.0008
Ríos	2,120	0.006	0.0002
Agua biológica	1,120	0.003	0.0001

El agua es uno de los elementos en constante dinamismo con la naturaleza, del cual se definen diferentes etapas, las que, por su manera de enlazarse, genera un verdadero ciclo; ya que su inicio ocurre donde posteriormente concluye. A este proceso se le conoce como “el ciclo hidrológico” que por definición es un proceso de abastecimiento de agua para los seres vivos. El fundamento del ciclo es que cada gota de agua, en cualquier etapa que se considere, recorre un circuito cerrado.

De las diversas fases del ciclo del agua (evaporación, condensación, precipitación, escorrentía, infiltración, transpiración, por mencionar los más comunes); la precipitación, en cualquiera de sus formas (agua o nieve), constituye la principal fuente de agua para la mayoría de los usos humanos y ecosistemas. Esta precipitación es recogida por las plantas y el suelo, un porcentaje se evapora en la atmósfera mediante la evapotranspiración, otro porcentaje se acumula en capas de hielo y en los glaciares y el otro va hacia escurrimientos superficiales, lagos o humedales (United Nations Educational, Scientific and Cultural Organization, 2003).

1.3 SITUACION ACTUAL DEL AGUA

La calidad del agua es de vital trascendencia en el consumo humano y en el uso doméstico, de ahí que su preservación y manejo deben ser una constante preocupación de los usuarios y las autoridades. Las aportaciones del ciclo hidrológico no ofrecen garantía, ya que dos tercios de la población mundial viven en zonas que reciben una cuarta parte de las precipitaciones anuales del mundo (Anaya Garduño, 2011). En la Figura 1 se muestra un mapa donde se observa de manera esquemática la distribución del promedio anual de precipitación.

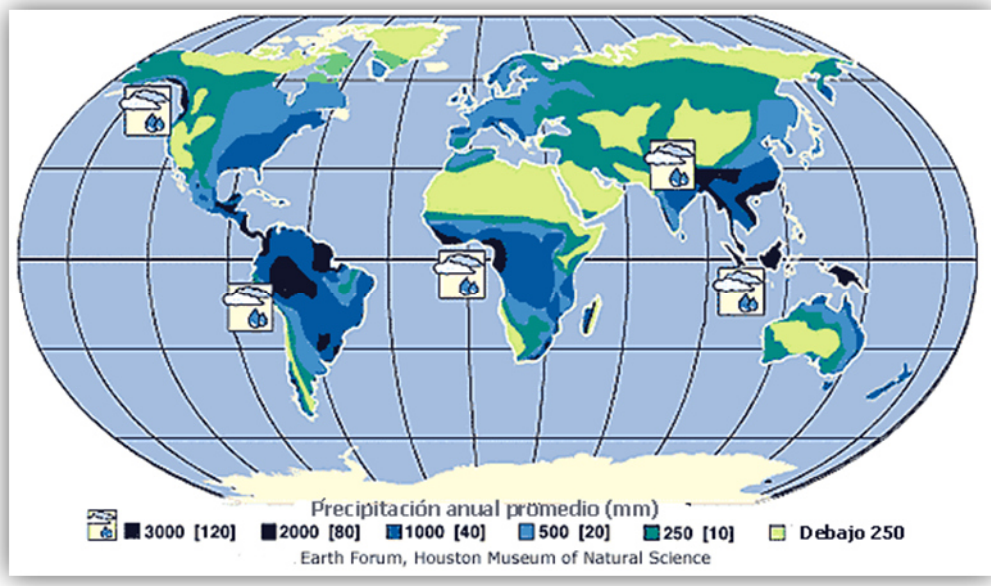

Figura 1 Distribución mundial de la precipitación anual promedio (mm)

El ser humano extrae un 8% del total anual de agua dulce renovable y se apropia del 26% de la evapotranspiración anual y del 54% del agua de escorrentía accesible. El control que la humanidad ejerce sobre el agua de escorrentía es ahora global y el hombre desempeña actualmente un papel importante en el ciclo hidrológico (United Nations Educational, Scientific and Cultural Organization, 2003).

Si a lo antes mencionado se le adjunta la creciente expansión demográfica, la escasez y el deterioro de la calidad del agua aumentaría la afectación de la salud y el bienestar de la población, en países en vías de desarrollo. Actualmente, en las regiones de África, Asia, América Latina y el Caribe, la escasez del agua dulce con adecuada calidad y cantidad está surgiendo como uno de los problemas más críticos que enfrenta la humanidad.

Las principales prioridades de la humanidad se refieren a la disponibilidad de agua segura, siguiéndole la alimentación (Actualmente el 70% del total de agua fresca se usa para producción de alimentos), lo cual se concluyó en los Foros Mundiales del Agua (IV y V) realizados en los años 2006 y 2009.

La competencia por el suministro de agua dulce produce problemas sociales, económicos y políticos. Las cuencas fluviales y otras masas de agua no respetan fronteras. Por ejemplo, al utilizar el agua, una región situada aguas arriba suele regularmente ignorar el suministro disponible para las regiones situadas aguas abajo.

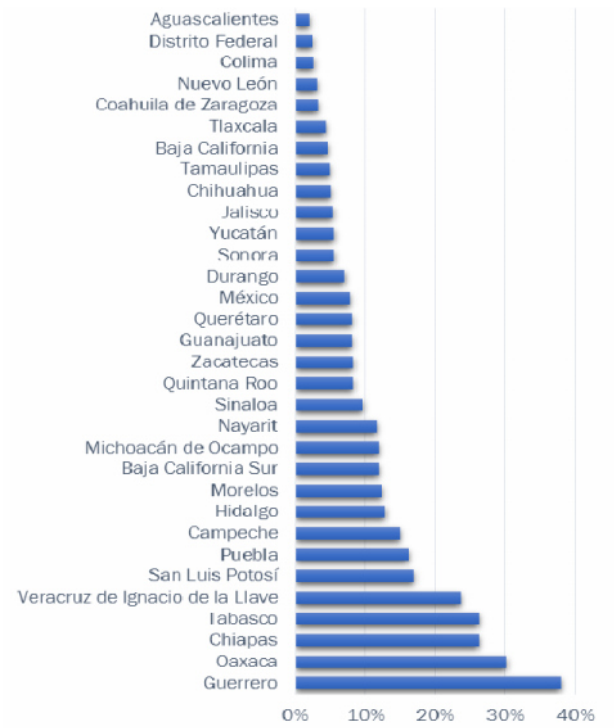

Figura 2 Porcentaje de viviendas sin acceso al agua entubada (INEGI, 2010)

En México, durante las últimas décadas, los problemas ambientales relacionados con el agua han aumentado tanto en zonas urbanas como rurales, y se tienen 3.6 millones de viviendas sin acceso al agua entubada, el abastecimiento de agua abarca un 94% de la población urbana y solo un 63% de la población rural. En relación con el saneamiento, éste llega a un 87% de la población urbana y solo al 32% de la población rural (Anaya Garduño, 2011); en la Fig. 2 se muestran los porcentajes de viviendas que no cuentan con agua entubada según el estado.

1.3.1 Causas del problema

Los problemas a los que se enfrenta la población, en la mayoría de los casos son causados por fenómenos naturales, socio-culturales y de índole política, al no tener una correcta gestión de los recursos hídricos actuales.

El cambio climático provoca una alteración en la recurrencia de fenómenos meteorológicos adversos, como sequías, inundaciones y huracanes, entre otros, repercute en el desarrollo de una población. En las últimas décadas debido a la importancia que se le ha dado al estudio de los fenómenos del cambio climático, se han analizado con gran atención los cambios que se pueden presentar en los climas globales y locales, especialmente en los puntos críticos del ciclo hidrológico.

Actualmente las alteraciones climáticas globales se atribuyen directa o indirectamente a la actividad humana, que altera la composición global atmosférica de una manera acelerada, agregada a la variabilidad climática natural observada en períodos comparables de tiempo.

Los estudios realizados por el Panel Internacional sobre Cambio Climático (IPCC, por sus siglas en inglés), indican que el ciclo del agua se verá afectado en los próximos años: cambiará la distribución de las lluvias y aumentará la frecuencia de condiciones atmosféricas extremas, tanto húmedas como secas (Ortega Guacín , 2012).

Uno de los eventos hidrometeorológicos que están tomando peso en el ámbito técnico-científico, debido a los estragos que ha causado el fenómeno en diferentes partes del mundo, por el impacto que tienen hacia los recursos hídricos de una región es la sequía, que se puede definir dependiendo del enfoque que se dé al efecto que produzca este fenómeno lo que da a la definición de “Sequía” un carácter local y regional, por lo que es vano pensar en generalizar la definición del concepto (Wilhite, 2000).

Por lo tanto, el cambio climático es un hecho y, aunque existen escépticos, éstos no representan de manera alguna un grupo mayoritario. Es por ello que los gobiernos, en el nivel mundial han reaccionado ante esta amenaza cada vez más cercana: las alteraciones climáticas graves que podrían colocar sus economías en peligro.

México no escapa de los impactos del cambio climático. Expertos del IPCC comentan que México es un claro ejemplo de las variaciones climáticas, por las frecuentes sequías que se presentan desde fines del siglo pasado (Ortega Guacín , 2012).

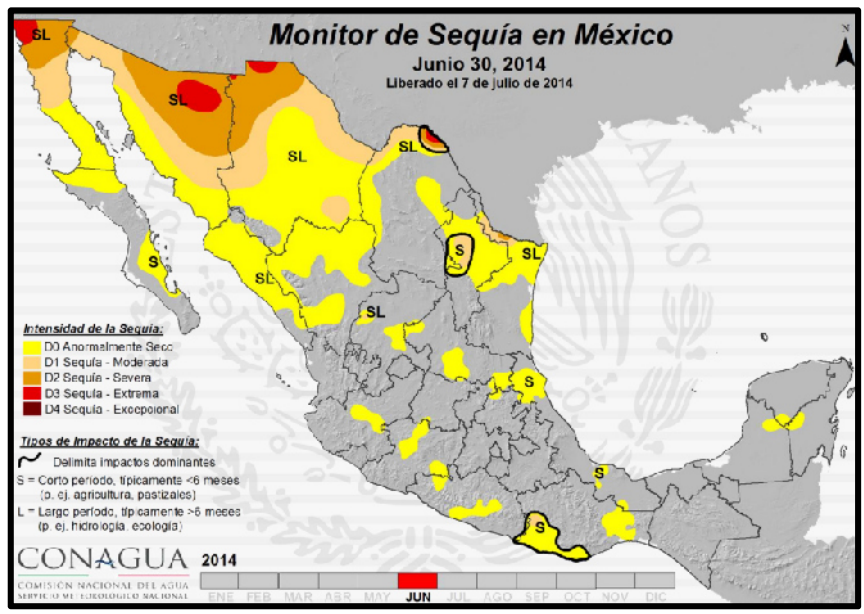

Figura 3 Monitoreo de Sequía en México, mes junio 2014

Nuevo León se encuentra en el noreste de México y en los últimos años se ha visto afectado por el fenómeno meteorológico de la sequía; como se observa en la Figura 4. El estado de Nuevo León reporta una intensidad de Sequía en el 48.71% de área total del estado, como “anormalmente seco”, y en el 10.52 % del área, de tipo “moderada”, dejando un 40.76% del área sin afectación del fenómeno.

1.4 QUÉ SE ESTA HACIENDO.

Como se ha mencionado, el crecimiento demográfico, la transformación de los estilos de vida y el desarrollo económico de los países en desarrollo han acentuado la presión sobre el problema del agua, sin dejar a un lado otros problemas ambientales como el cambio climático, que ejercen una presión extra sobre este recurso (Anaya Garduño, 2011).

Una de las acciones para resolver los problemas hídricos, que están mayormente relacionados con la estructura de la economía mundial, es que muchos países han externado significativamente su huella hídrica, al importar bienes donde requieren un alto contenido de agua para su producción. Este hecho genera una importante presión sobre los recursos hídricos en las regiones exportadoras, que son más vulnerables, donde a menudo se carece de mecanismos de gestión y conservación de los recursos hídricos (Lambarri Beléndez & Uribe Visoso, 2012).

Existen diversos estudios que indican que la captación de agua de lluvia constituye una solución para el abastecimiento de agua, ya que se ha convertido en una medida amigable económica y ecológicamente en la gestión de agua urbana. La captación de agua de lluvia se puede utilizar para suministrar agua adicional en inodoros, jardinería, refrigeración y en sistemas de aire acondicionado de uso doméstico; además, ayuda a disminuir la carga de las tuberías de drenaje y evita la inundación por la detención y retención de agua pluvial por los tanques de almacenamiento. Otras veces, en las instalaciones de

infiltración también se implementan sistemas de captación como parte de un sistema de recolección de agua para la recarga de aguas subterráneas y, por tanto la restauración del ciclo hidrológico en la zonas urbanas (Hyoungjun , et al., 2012).

1.4.1 Sistemas de captación de lluvia (SCALL)

Se puede definir a la captación pluvial como la recolección del escurrimiento de lluvia sobre una superficie para propósitos de aprovechamiento. El concepto hace énfasis en el almacenamiento del agua de lluvia para su utilización posterior. La captación de agua de lluvia puede considerarse como una forma rudimentaria de riego, usando surcos, canales, etc. La diferencia es que la idea de la captación está en el control sobre la aplicación del agua colectada y no está sujeta únicamente al momento en el que llueve.

Existe conocimiento sobre una gran variedad de técnicas relacionadas con sistemas de captación y aprovechamiento de agua de lluvia. Dichas técnicas se pueden clasificar con base en sus diferentes fuentes, el tipo de escorrentía, las técnicas de manipulación, el tipo de almacenamiento y los diferentes usos que se le da al recurso (García Velázquez, 2012). En la Figura 3 se muestra un esquema de la clasificación de SCALL, en función de la escala que tenga el sistema.

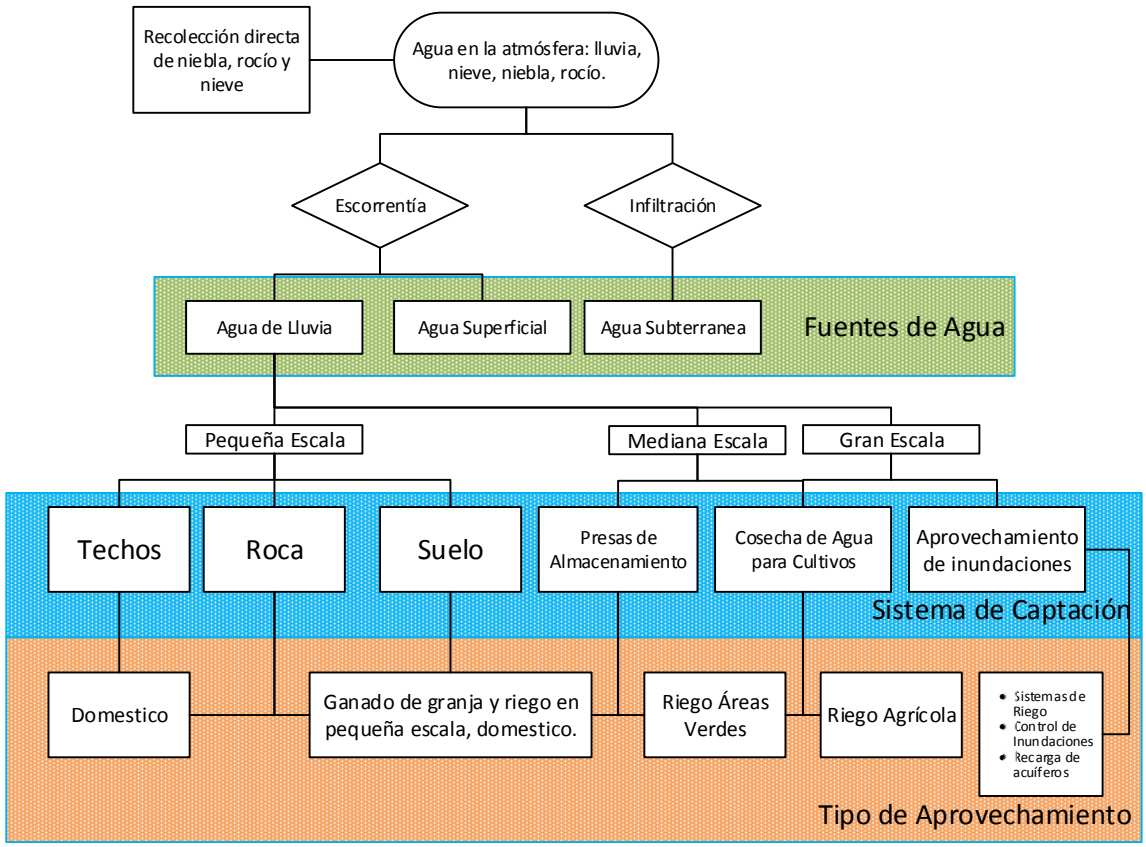

Figura 4 Clasificación general de los sistemas de captación de lluvia (García Velázquez, 2012)

1.4.1.1 Antecedes y condiciones actuales de los Sistemas de Captación de Lluvia en México.

A pesar de que México es un país que tiene una disponibilidad de agua de lluvia per cápita promedio de 4,750 metros cúbicos por año, cantidad suficiente para abastecer a la población, existe una distribución desigual en el espacio y el tiempo, así como la escasez de agua con la calidad requerida para los diferentes usos, y esto origina frecuentes conflictos entre los usuarios y las regiones.

Existen vestigios del año 300, a.C., en la zona arqueológica de Yucatán, que muestran cómo se emplearon los sistemas de captación conocidos como “Chultún”, que tenían la función de recolectar el agua de lluvia de los patios y conducirla a depósitos construidos de piedra, para ser utilizada posteriormente.

En épocas recientes, el crecimiento acelerado de la población mundial está ejerciendo presión sobre las fuentes finitas de agua. Por ello, en las últimas dos décadas, el interés por la captación del agua de lluvia se ha incrementado. Mientras que en algunas regiones nunca se ha dejado de utilizar el agua de lluvia debido a la escasez de otras fuentes, como el caso de islas volcánicas y zonas áridas, en otros sitios su uso se está expandiendo rápidamente, particularmente en países en vías de desarrollo de África y Asia (Guold & E. Nissen-Petersen, 1999). Según Ballén (2006), la mayor parte de los sistemas de aprovechamiento de agua de lluvia son el resultado de 3 factores principales:

• La necesidad y demanda del recurso hídrico

• Las condiciones disponibles: la precipitación pluvial, el costo de la inversión y las características de los materiales de construcción

• Las condiciones sociales y ambientales de cada región.

En 2012, en el XXII Congreso Nacional de Hidráulica, en Acapulco, Guerrero, México, Gómez Lugo Luis, del Instituto Mexicano de Tecnología del Agua presentó un estudio sobre el potencial de aplicación que tendrían los sistemas de agua de lluvia en las diversas escuelas del estado de Morelos.

Dicha investigación tuvo como fin presentar resultados de áreas de captación y volúmenes de almacenamiento para los diferentes tipos de escuela. Con el fin de promover una línea de trabajo solida sobre el aprovechamiento del agua de lluvia en las escuelas del Estado de Morelos, para que en un futuro cercano se exploren las sinergias de programas y proyectos desde los diferentes sectores (Gobierno, iniciativa privada y sociedad).

Los criterios que analizó correspondieron a una dotación de 6 litros por alumno por día, al igual que analizó diversos escenarios, cambiando el número de alumnos desde 60 hasta 300, con un incremento de 60 alumnos. Resumió sus resultados en una tabla de recomendaciones donde reportó el volumen de la cisterna, el tiempo de implementación, una estimación del tiempo de la mano de obra y una aproximación de materias, ver la Tabla 2. Concluyó recomendando que la investigación se realice en un nivel nacional con el fin de obtener un banco de información útil para la Secretaria de Educación Pública (SEP), Comisión Nacional de Agua (CONAGUA) y demás instancias relacionadas con la gestión der recursos hídricos en las escuelas de México, lo cual favorecería el fortalecimiento de la cultura de captación y almacenamiento de agua de lluvia en México (Gómez Lugo, 2012).

Tabla 2 Recomendaciones asociadas con la implementación de cisternas de diferentes capacidades (Gómez Lugo, 2012).

Volumen cisterna [m^3]	**Tiempo de implementación** [días]	**Mano de obra** [Jornales/día]	**Inversión (materiales)** [$ X 10^3]
50	8 – 12	8 - 10	18 - 20
100	15 – 25	10 - 12	33 - 36
500	30 – 40	12 - 15	140 - 160
1,000	50 – 75	15 - 20	250 - 280

El Centro Internacional de Demostración y Captación en Aprovechamiento del Agua de lluvia (CIDECALLI) realizó el proyecto COLPOS 1, que consiste en un esquema base de captación de agua de lluvia que demuestra como una familia de 4 personas se puede abastecer de agua potable, con un consumo per cápita de 100 litros diarios, durante el periodo de sequía, con un área de captación de 102 metros cuadrados, estimando una precipitación pluvial anual de 610 mm y un tamaño de almacenaje de 3 metros cúbicos. Con un costo de inversión de $35,000 pesos mexicanos. En la Figura 5 se muestra el esquema base que se presentó en un artículo de la revista internacional “Sostenibilidad, Tecnología y Humanismo”, en una investigación de Margarita Pacheco (Pacheco Montes, 2008).

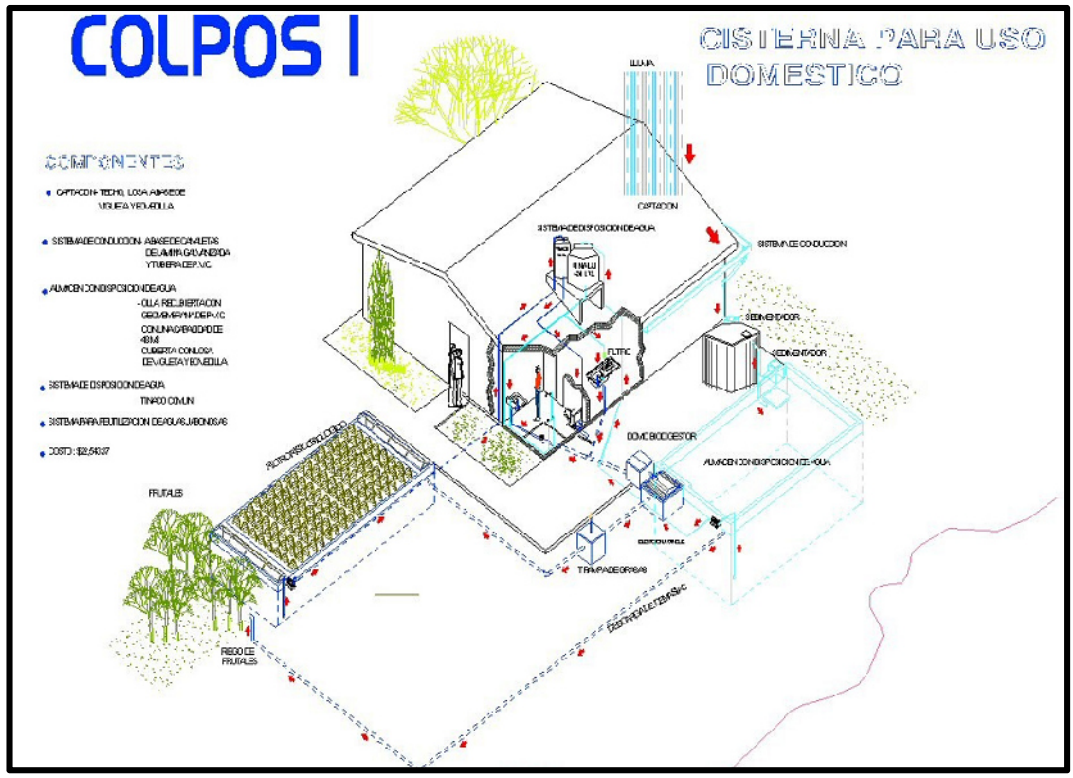

Figura 5 Esquema COLPOS I (Pacheco Montes, 2008)

Entre otros proyectos que presentan son sistemas de Captación y purificación de Agua de Lluvia para consumo humano en tres comunidades de la meseta tarasca del Estado de Michoacán. En dichos proyectos se utilizaron los techos de escuelas de las comunidades de Santa Rosa, San Isidro y San Antonio en el municipio de Los Reyes, Michoacán.

1.5 JUSTIFICACÓN DE ESTE ESTUDIO.

Es necesario realizar una adecuada gestión del agua, en relación con la conservación, el manejo y el desarrollo de los recursos hídricos, que incluya diversos enfoques, acciones y actividades para hacer frente ante los crecientes problemas que existen sobre la falta de agua, y qué mejor manera de empezar que por el propio hogar.

El desarrollo urbano trae como consecuencias mayor número de superficies impermeables, que se han traducido en el aumento de casos de inundaciones y sequías en todo el mundo. El diseño actual de la gestión de agua urbana se basa primordialmente en el control de aguas abajo, ya que este enfoque es más económico que el control de las fuentes de escorrentía. Sin embargo, debido a los cambios climáticos, dichas medidas de gestión se han vuelto ineficaces. (Urbonas & Stahre, 1993)

La precipitación pluvial, es la principal fuente de agua para la mayoría de los usos humanos y los ecosistemas; por lo que, aprovechar esta fuente a través de la captación, ha representado una opción para abastecer de agua a regiones donde las fuentes de agua están contaminados y/o se encuentran sobreexplotados (Anaya Garduño, 2011). La aceptación de un SCALL depende de la cantidad y la calidad que ofrezca el sistema (Fewkes, 2012), y estos factores dependen de la ubicación donde se pretende implementar el sistema de captación, ya que cada región tiene sus características peculiares, en cuanto a

la distribución de la precipitación y la presencia de contaminantes ambientales que afectan directa o indirectamente la eficiencia del SCALL.

Actualmente, la implementación de los SCALL en las viviendas ha tenido aceptación en la zona centro y sur del país de México, al tener estas regiones un clima húmedo, donde llueve la mayor parte del año; en cambio, el norte del país es una zona más árida, por lo que los criterios aplicados en cuanto al efecto de las primeras lluvias en la calidad y la calidad misma del agua de lluvia en las zonas antes mencionadas no son muy aplicables en la región en estudio.

1.6 OBJETIVOS DEL PROYECTO.

1.6.1 Objetivo general

Evaluar la implementación de Sistemas de Captación de Agua Meteórica en pequeña escala (Techumbres) en la Zona Metropolitana de Monterrey como medida para prevenir o mitigar los riesgos que se presentan ante los fenómenos adversos a los que está expuesta la ciudad.

1.6.2 Objetivos Particulares:

1. Realizar un análisis espacial sobre la implementación de SCALL en las áreas habitacionales de la Zona metropolitana de Monterrey, para determinar una distribución en la cantidad de agua que se puede

captar, de acuerdo con la distribución de la precipitación, sobre una representación gráfica (Mapa).

2. Elaborar el diseño preliminar de los elementos de un Sistema de Captación de Agua de Lluvia en el laboratorio de hidráulica de la Facultad de Ingeniería Civil de UANL, con los datos obtenidos del análisis espacial, tomando en cuenta los parámetros presentes en la zona.

1.7 HIPOTESIS

Al implementar Sistemas de Captación de Agua de Lluvia (SCALL) en una urbe con un constante riesgo por los efectos de los cambios extremos en el clima, como los periodos largos de la temporada seca y los periodos con lluvias intensas, se esperará tener resultados favorables, en diversos niveles, tanto social como ambientalmente, ya que se llegaría a tener un impacto en cuanto a la dotación de agua proveniente de las fuentes de abastecimiento actuales, utilizando el agua para riego de jardines descargas sanitarias, lavado de autos y otras actividades que no requieran la potabilización de alta calidad.

CAPÍTULO 2

EL MARCO TEÓRICO.

El empleo de sistemas de captación de agua de lluvia (SCALL) se remonta a épocas históricas, como en la región de la Mesopotamia, donde se tienen registros con más de 5000 años. Conforme el crecimiento de los asentamientos humanos y las innovaciones en la extracción, y el traslado del agua de fuentes superficiales y subterráneas, esta práctica fue perdiendo importancia.

Como se ha mencionado con anterioridad y en diversos congresos sobre el tema del agua, una de las prioridades de la humanidad es la de asegurar el recurso hídrico a toda la población, tanto en cantidad como en calidad.

Por lo tanto, la gestión del agua en las ciudades es crucial, ya que el uso de este recurso está lejos de ser sostenible; pues el principal problema es la creciente demanda de este recurso, lo que trae una gran presión sobre las fuentes de abastecimiento disponibles.

La captación de agua de lluvia se presenta como una guía sostenible que puede ser incluida dentro de la gestión del ciclo urbano del agua. Presenta muchos beneficios; por ejemplo, puede reducir la demanda externa de agua de

la ciudad, aliviar el estrés de agua en la zona, reducir el volumen tratable de escorrentía urbana, evitar inundaciones y ayudar a aliviar el cambio climático.

De igual manera, dado al bajo nivel de complejidad tecnológica, estos sistemas son fácilmente adaptables a diversas condiciones ecológicas en donde la precipitación pluvial es mayor que 200 mm anuales.

El agua de lluvia es de muy alta calidad, mientras que esta precipita y llega a la tierra; sin embargo, cuando la precipitación entra en contacto con una variedad de superficies y paisajes, (cuerpos de agua, superficies antropogénicas como techos y estacionamientos) se pueden adicionar contaminantes en el escurrimiento del agua meteórica (Despins, 2012), debido a que la precipitación es un mecanismo natural de limpieza debido a la remoción de compuestos atmosféricos solubles; por tal razón, la calidad del agua meteórica es importante por diversas razones:

- La contaminación presente en las aguas meteórica urbanas es una de las principales fuentes de deterioro de los cuerpos de agua receptores, principalmente los lagos y los ríos, cercanos a grandes ciudades (U.S.EPA, 1990) (Montt, et al., 2003).
- La aceptación de un sistema de captación de lluvia para el usuario está relacionada con la calidad del agua expresada en las condiciones que se presenta, como son el color, el olor y la turbiedad. La calidad microbiológica del agua puede determinarse por el riesgo

potencial para la salud que represente el sistema para el usuario (Fewkes, 2012)

- La comparación de los índices de contaminación observados con otras zonas donde ya se realizaron estudios relacionados.

La presencia de contaminantes en la precipitación o escorrentía del agua, puede afectar las propiedades físicas, químicas y/o biológicas del agua y, si éstos están presentes en cantidades suficientes, pueden afectar la estética y la calidad del agua (su color, sabor y olor) y / o producir impactos negativos en la salud humana. Por estas razones, la calidad del agua meteórica es uno de los factores clave que determinan su idoneidad para cada uso particular (Despins, 2012).

La contaminación de agua meteórica se origina de 4 fuentes principales:

1. Contaminación de la precipitación durante su paso a través de la atmósfera “deposición húmeda”. (Mottier et al, 1995; Thomas y Greene, 1993; Zobrist et al, 2000)
2. Deposición seca de los contaminantes atmosféricos sobre la superficie de captación durante periodos secos.
3. Reacción química y/o física del agua meteórica en contacto con la superficie del material de recolección y/u otro componente del sistema, por ejemplo, el tanque de almacenamiento.
4. Heces de aves y animales depositadas sobre los techos.

Las primeras 3 fuentes potenciales de contaminación afectan las características químicas y/o físicas del agua meteórica, mientras que la última determinará la su calidad microbiológica (Fewkes, 2012).

La modelación cuantitativa de la contaminación de agua meteórica urbana es compleja, debido a la enorme cantidad de variables que participan, la aleatoriedad de su comportamiento y las dificultades para conocer con razonable precisión algunos de los procesos. En la Tabla 3 se muestran algunos de los parámetros que participan y que pueden determinarse con o sin dificultad.

Tabla 3 Nivel de dificultad para determinación de las variables

	Parámetros
Sin Dificultad	La magnitud de la lluvia.
	La duración del Evento.
	La intensidad de la lluvia.
	El tiempo seco entre tormentas.
	El área de la cuenca.
	Los tipos de uso de suelo.
	Las frecuencias de lavado de calles y techos.
Con Dificultad	La acumulación de contaminantes durante el tiempo seco.
	Los efectos de viento.
	La granulometría de los sedimentos.
	La infiltración.
	La erosión de las zonas permeables.
	La capacidad de lavado.

Las características químicas y físicas del agua meteórica recogida de los techos han sido investigada por un número de profesionistas que incluye Sazakli et al. (2007) y Vásquez et al. (2003). Los valores reportados por Mottier et al. (1995), Foster (1991), Yaziz et al. (1989), Xanthopoulos y Hahn (1994) y Surrendran y Wheatley (1998) se resumen en la siguiente Tabla II:

Tabla 4 Resumen de los datos de calidad del agua de escorrentía

	pH	BOD(mg/l)	COD(mg/l)	TOC	Turbiedad(mg/l)	TS(mg/l)	SS(mg/l)
Escorrentía en Techo	5.2-7.9	7-24	44-120	6-13	10-56	60-379	3-281
Escorrentía Almacenada	6-8.2	3	6-151	-	1-23	34-421	0-19

Las cargas contaminantes en la escorrentía de los techos son atribuibles principalmente a los contaminantes atmosféricos que se acumulan en los tejados como deposición seca o son removidas de la atmósfera por la lluvia y la deposición húmeda (Mottier et al, 1995; Thomas y Greene, 1993; Zobrist et al, 2000). Sin embargo, el material de cubierta puede influir en las características químicas y físicas de la escorrentía del agua meteórica.

CAPÍTULO 3

MARCO METODOLÓGICO

Para la evaluación de un Sistema de Captación de Agua de Lluvia SCALL, hay diversos aspectos importantes para tomar la decisión de implementar un SCALL en la comunidad. Esta investigación se centró en un análisis espacial para estimar el volumen de agua de lluvia que puede ser captado en la Zona Metropolitana de Monterrey, con el fin de analizar si es lo suficientemente rentable implementarlos como para tener un impacto positivo en el desarrollo integral de la sociedad.

3.1 ZONA EN ESTUDIO

El área en estudio es la Zona Metropolitana de Monterrey en el estado de Nuevo León. Dicha Zona incluye los Municipios de Monterrey, Apodaca, Cadereyta Jiménez, General Escobedo, García, Guadalupe, Santiago, Santa Catarina, San Nicolás de los Garza, San Pedro Garza García y Salinas Victoria (SEDESOL et al, 2007)

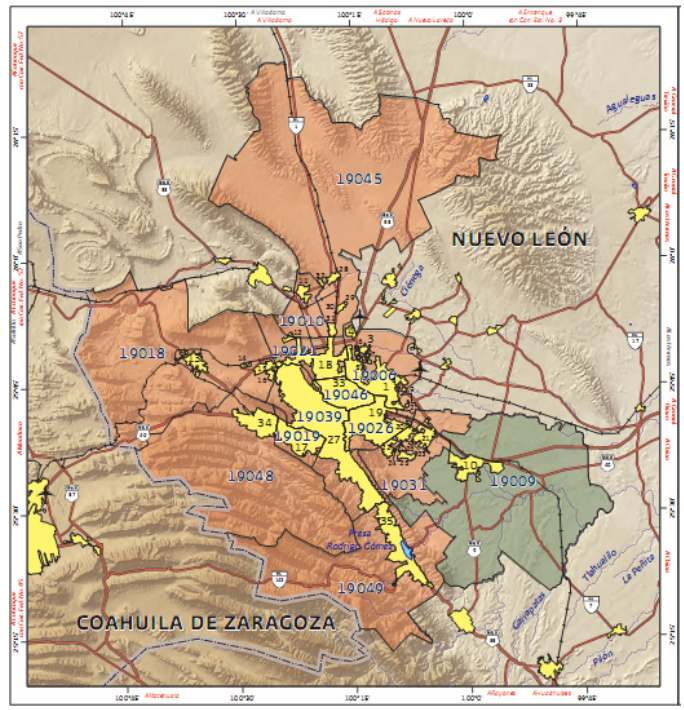

Figura 6 Zona Metropolitana de Monterrey (INEGI, 2010)

El principal objetivo es determinar una oferta que se pueda obtener del agua de lluvia al captarla en la zona metropolitana de Monterrey con el fin de disminuir el impacto que se tiene sobre las fuentes de abastecimiento de la ciudad de Monterrey, El criterio utilizado para determinar la demanda es que en todas las viviendas de la zona urbana se puede implementar un sistema de captación de agua.

3.2 ANÁLISIS DE INFORMACIÓN PLUVIOMÉTRICA.

El estudio tiene su base en el tratamiento de información pluviométrica de las Estaciones Climatológicas de Nuevo León, descrito en una investigación que consistió en la actualización de la base de datos, el cálculo de datos faltantes, las pruebas de calidad de datos y homogeneidad (Guzman,2014) .

Con el apoyo del software ArgGIS ®, se realizó el análisis espacial de los datos de precipitación media y precipitación neta, creando mapas de isoyetas y observando la distribución de la cantidad de precipitación que se presenta en el estado.

La precipitación neta se obtuvo a través del método descrito por Anaya Garduño, en el que se define como la cantidad de agua de lluvia que queda a disposición del sistema de captación de la lluvia. El cálculo de la precipitación neta está descrito en la siguiente ecuación 1

$$PN = \sum_{j=1}^{n} Pj \quad \eta \; ; Pj \geq 40\, mm \qquad (1)$$

Donde: PN= Precipitación Neta;

Pj= Precipitación Media Mensual;

η= Coeficiente adimensional (0.85).

El coeficiente representa el porcentaje de precipitación neto, debido a que se descuentan los porcentajes de las pérdidas por factores como salpicamiento, velocidad del viento, evaporación, fricción, tamaño de la gota. Se utilizó el valor de 0.85, que representa un 85 por ciento de precipitación media mensual, cumpliendo lo recomendado por el Centro Internacional de Demostración y Captación de Aprovechamiento del Agua de Lluvia. Se calculó la Precipitación Neta para cada una de las estaciones climatológicas del Estado de Nuevo León tomando la condición de sumar sólo los meses que reporten más de 40 mm de precipitación. De igual manera, se realizó el registro contando los meses que pasan esta cantidad y los que no, que se denominaron como meses húmedos los meses con una altura de precipitación mayor que 40 mm. Por lo que se crearon mapas con la distribución de la Precipitación Media Anual y Precipitación Neta Anual.

3.3 ÁREAS DE CAPTACIÓN.

Se determinaron las áreas que podrán servir para captar el agua de lluvia. Este análisis se realizó considerando que es posible tomar los techos de las viviendas de la zona metropolitana de monterrey como áreas de captación, por lo que se procedió a estimar el área total de los techos de las viviendas, para así estimar un volumen de agua captado.

La información se recabó del Sistema para la Consulta de Información Censal (SINCE), que es una herramienta creada por Instituto Nacional de Estadística y Geográfica (INEGI), que permite asociar la información estadística

del Censo 2010 con el espacio geográfico al que pertenece, con lo cual aporta información complementaria para facilitar la interpretación de los fenómenos sociodemográficos.

La serie de los indicadores sociodemográficos está representada, por entidad federativa, municipio, localidad, áreas geo estadísticas básicas (AGEB), manzanas urbanas y zonas metropolitanas; en un archivo tipo Shape. La información utilizada para este estudio fue en un nivel de desagregación de Manzanas, donde la base de datos indica el número de habitantes existente en la manzana, así como el número de viviendas habitadas, el de habitantes por vivienda y el número de viviendas que no cuentan con el servicio de agua entubada, entre otros datos socioeconómicos por Manzana; es decir, muestra un mapa de las manzanas existentes en los municipios que comprenden la zona metropolitana de monterrey, con la información antes mencionada. Con estos datos se puede elaborar un mapa temático que indique algunos de los parámetros seleccionados, según la finalidad del estudio a realizar.

Ahora bien, con la información disponible se observa que existe una variación en el tamaño y el material del techo de las viviendas en la zona metropolitana, por lo que se realizaron las siguientes consideraciones:

1. Se seleccionaron las manzanas en las que se reporta que existen viviendas con habitantes.

2. Se multiplicó el área correspondiente a la manzana por un coeficiente de 0.83. Dicho valor se propuso para disminuir el área verde, suponiendo que las

zonas habitacionales cumplan el 17% del área verde que dicta la Ley de Desarrollo Urbano del Estado de Nuevo León en su Artículo 201; esto con el fin de obtener el Área Efectiva de Captación.

3.- Se generalizo el material del Techo a losa de concreto, con el fin de unificar el coeficiente de escurrimiento en el área de captación (C=0.9).

De la información obtenida se descartaron aquellas manzanas en las que no se presentarán viviendas. Una vez realizado lo anterior, se procedió a calcular el Área Efectiva de Captación, multiplicando el área total de las manzanas seleccionada, por el coeficiente 0.83.

3.4 VOLUMEN CAPTADO.

Cuando ya se conoce la magnitud de una superficie fija que será destinada para la captación del agua de lluvia; tal es el caso de los techos de casas, de escuelas, de industrias, etc.; el razonamiento del diseño de un SCALL está dirigido a calcular el volumen de agua que puede ser captado en esta superficie y definir la capacidad para cubrir una demanda. Para determinar dicha capacidad se planteó la siguiente ecuación con los datos obtenidos en puntos anteriores:

$$Vol = \frac{PNA \quad Ae \quad CE}{1000} \qquad (2)$$

Donde: Vol.= Volumen captado en m^3;

PNA= Precipitación Neta Anual en mm;

Ae= Área efectiva de captación en m²;

CE= Coeficiente de Escurrimiento adimensional.

Con los datos obtenidos en los puntos anteriores se generaron mapas con la distribución de la Precipitación Neta Anual (PNA) y con las manzanas indicando el Área Efectiva de Captación de cada una de ellas. Se observó que se tenían dos representaciones: una que indicaba cómo se distribuye la cantidad de precipitación y otra la distribución de las manzanas con la información del área efectiva. Se realizó con ayuda del Software ArgGIS ®, una combinación de estos archivos para determinar la Precipitación Neta Anual Promedio presente en cada manzana, y para realizar el cálculo del Volumen Captado por cada manzana seleccionada.

3.5 DISEÑO DE LOS ELEMENTOS DE UN SCALL

El diseño de un sistema de captación de lluvia se basa en el dimensionamiento de cada uno de los componentes, contemplando los factores externos que lleguen a afectar el funcionamiento del mismo.

Se tuvo la facilidad de resolver este caso en el Laboratorio de Hidráulica de la Facultad de Ingeniería Civil, de la Universidad Autónoma de Nuevo León. Los componentes a diseñar fueron: el dimensionamiento de los tanques de primeras lluvias, debido al efecto de lavado natural de la atmósfera y de las superficies de contacto que los primeros milímetros de lluvia recogen, y al ver que esto puede alterar la calidad del agua de los cuerpos receptores es necesario plantear unos

contenedores de este volumen que requiere de otro tratamiento para mejorar su calidad, para posteriormente enviarlo a la cisterna que contendrá el agua que se captó. El diseño se realizó en función de las condiciones actuales de la zona en estudio.

3.5.1 La Zona de Estudio.

Se consideró como zona de estudio el laboratorio de Hidráulica de la Facultad de Ingeniería Civil de la Universidad Autónoma de Nuevo León, ubicado al norte del campus de Ciudad Universitaria, en el municipio de San Nicolás de los Garza, Nuevo León.

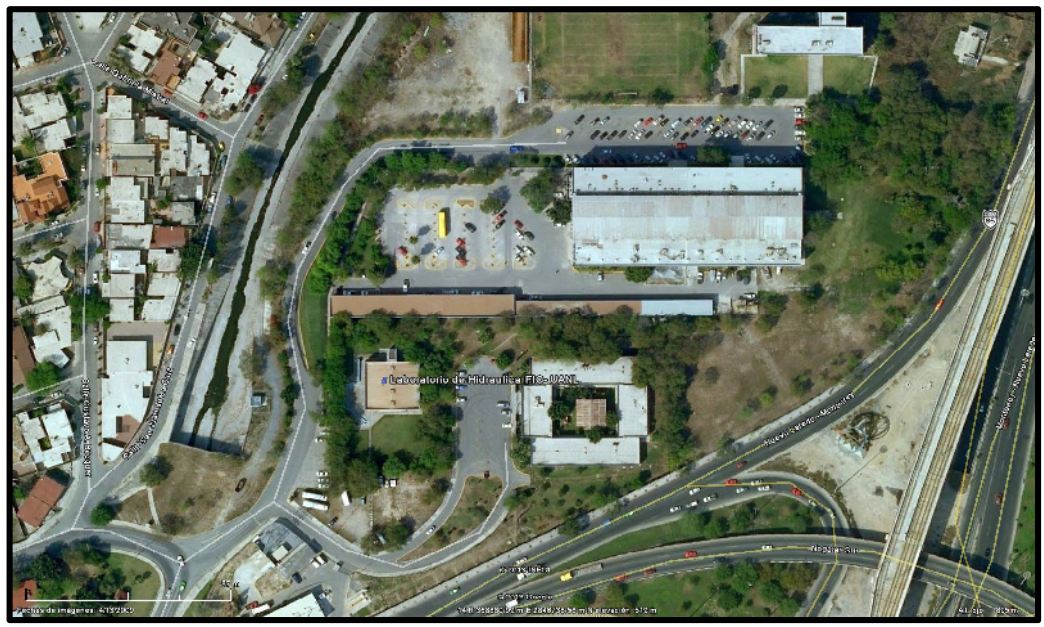

Figura 7 Vista aérea del laboratorio de Hidráulica de la FIC-UANL (Google Earth 2015)

El edificio del laboratorio se encuentra rodeado de vegetación alta y cuenta con un drenaje pluvial que consiste en dos canaletas de acero, situadas a lo largo de los costados del laboratorio y en cada una se conectan 3 bajadas pluviales del mismo material que conectan a un registro ubicado debajo de cada una y estos registros se conectan para descargar al drenaje sanitario.

La superficie total de la techumbre es de 500 m^2, dividida por un parteaguas en el centro; la pendiente del techo es de 0.0865 y está recubierta por un impermeabilizante, lo que le da poca rugosidad al techo teniendo un coeficiente de escurrimiento de 0.9

Se recomienda ver Anexo 1 para referencia de las condiciones de la techumbre del laboratorio de hidráulica, al igual que observa la instalación de un pluviómetro para determinar con mayor exactitud la cantidad de precipitación presente en la zona del laboratorio.

3.5.2 El contenedor de primeras lluvias.

El criterio para el diseño de este componente en el Sistema de Captación de Lluvia se basó en lo encontrado en investigaciones previas, en las que evalúan cómo varían los agentes contaminantes en la lluvia conforme continúa lloviendo. La finalidad de incluir este componente es almacenar el agua con mayor contenido de contaminantes y separarla del agua que tuviese mejor calidad para mandarla a la cisterna del sistema.

Diversos autores proponen que el diseño de este contenedor debe hacerse considerando un volumen de lavado de 1 litro por metro cuadrado de captación,

lo que equivale a los primeros milímetros de precipitación (Hernández & Villa Cisneros , 2013). De acuerdo con proyectos elaborados por Isla Urbana, en el Sur del país, se ha implementado que el volumen a separar corresponde a los primero 2 milímetros, para zonas urbanas y el primer milímetro, en zonas rurales por metro cuadrado de captación .Esto con el sustento de que se presenta mayor contaminación en las zonas urbanas que las zonas rurales. (García Velázquez, 2012). De igual manera se estipula que por cada mililitro de lluvia desviado se aumenta un 50 % más la calidad, en promedio (Martinson & Thomas, 2010).

Por lo anterior, para este estudio se consideró 1.5 milímetros por metro cuadrado de techo, para determinar el volumen que deben de captar dichos contenedores y realizar un diseño adecuado a la calidad que se espera obtener, ya que el principal uso seria como agua “gris”.

3.5.3 La cisterna de almacenamiento.

Este componente se calculó con base en el valor de Precipitación Neta Anual obtenido en la zona del Laboratorio. Este laboratorio cuenta con una cisterna que tiene una capacidad de 80 metros cúbicos. El objetivo que se buscó que almacenar la mayor parte posible del agua que se puede captar en una cisterna aparte, con el fin de contabilizar el volumen captado por el sistema. El objetivo primordial de aplicar un sistema de captación de agua de lluvia es obtener un sistema mixto en el que se pueda utilizar el agua de lluvia y el agua del drenaje para, en una investigación futura, evaluar el impacto del sistema a las labores cotidianas del laboratorio.

CAPITULO 4

RESULTADOS Y DISCUSIÓN.

4.1 MAPAS DE PRECIPITACIÓN MEDIA ANUAL Y PRECIPITACIÓN NETA ANUAL.

Como se mencionó en el apartado del método, se realizó el análisis de la Precipitación Neta Anual que reportaría cada una de las estaciones Climatológicas del Estado de Nuevo León, por lo que se creó una base de datos que facilitó el cálculo de la Precipitación Neta, donde se indicaron los criterios expuestos en la fórmula 1, los meses con precipitaciones mayores que 40 mm, por lo que se contabilizaron los meses con esta característica y se les consideraron húmedos y, por consecuente a los que reportaron menos de 40 mm , como secos; esto con el fin de indicar qué meses tienen una aportación considerable en el sistema de captación de lluvia. A continuación se presenta en la Tabla 5 un resumen de la base de datos utilizada para realizar la distribución de precipitaciones netas anuales. Para mayor detalle ver el Anexo 2.

Tabla 5 Resumen de cálculo de Precipitación Neta Anual (mm) para algunas estaciones climatológicas del Estado de Nuevo León

Una vez completa la base de datos con los datos de PNA y los periodos de meses Húmedos y Secos, se realizó los mapas de distribución con la ubicación de las estaciones y una interpolación IDW que está basada principalmente en la inversa de la distancia elevada a una potencia matemática, es decir, determina los valores de celda a través de una combinación ponderada linealmente de un conjunto de puntos de muestra. La ponderación es una función de la distancia inversa. La superficie que se interpola debe ser la de una variable dependiente de la ubicación. Tal es el caso de los valores de precipitación neta. (Esri, 2012).

En las Figuras 8 y 7, se observa cómo varia la precipitación dentro de la zona metropolitana, indicando la zona con mayor cantidad de precipitación, es al sur del municipio de Monterrey, junto con los municipios de Cadereyta Jiménez y Santiago, siendo este último el municipio donde está ubicada la presa Rodrigo Gómez.

Por otra parte, en la zona Noroeste del área metropolitana de monterrey se encuentran en los municipios de García y de Salinas Victoria que son los municipios que reportan una menor cantidad de precipitación. Esto implica que se tendrían algunas dificultades para ver la utilidad de un sistema de captación de lluvia en esas zonas, debido a que al realizar el cálculo de la precipitación neta se reportaron valores inferiores a 100 mm de lluvia en esas zonas, dejando a un lado que tiene mayor recurrencia de meses secos, de acuerdo con el criterio mencionado anteriormente.

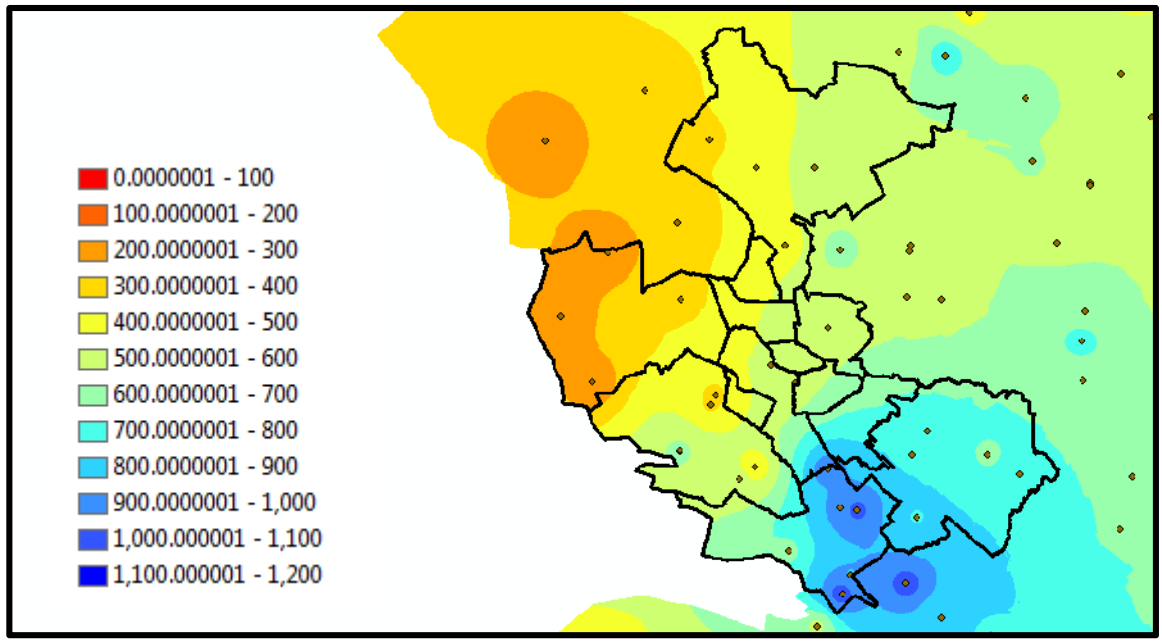

Figura 8 Mapa de le Distribución de la Precipitación Media Anual (mm) de la Zona Metropolitana de Monterrey

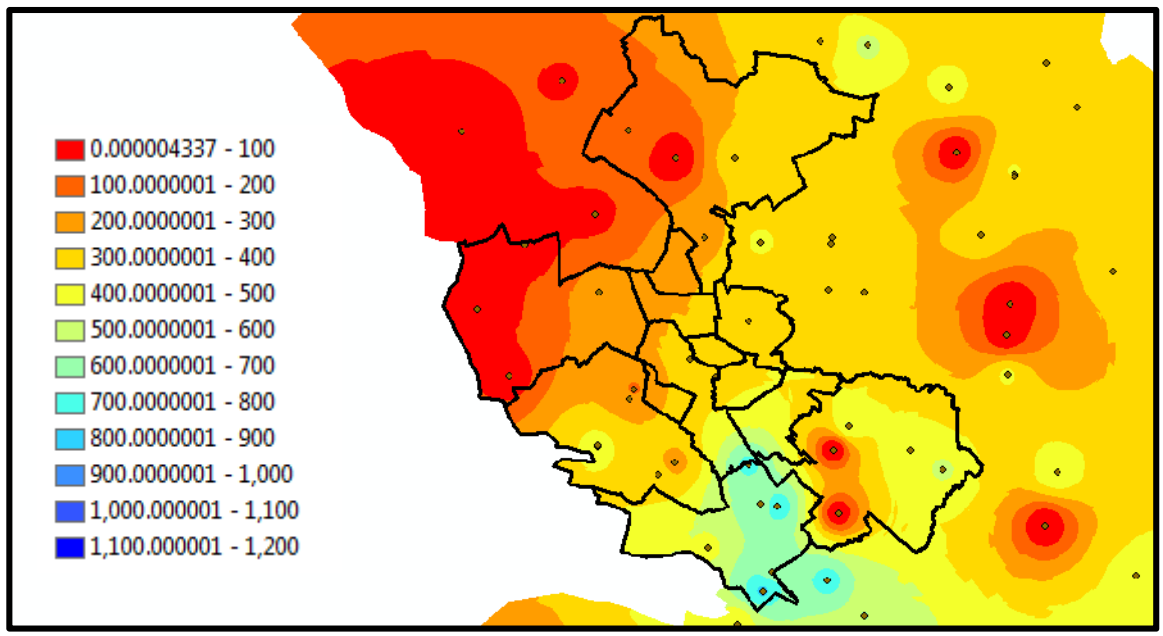

Figura 9 Mapa de la Distribución de la Precipitación Neta Anual (mm) de la Zona Metropolitana de Monterrey

4.2 VOLUMEN A CAPTAR EN LA ZONA METROPOLITANA DE MONTERREY.

El resultado del análisis del volumen de captación se obtuvo en el mismo nivel en el que se encontró la información en Sistema para la Consulta de Información Censal (SINCE); es decir, se obtuvo el volumen posible a captar por cada manzana con viviendas, y donde se puede aplicar un sistema de captación.

Al ser una base de datos extensa la Tabla 6, se presenta una pequeña parte de los resultados obtenidos mostrando unas cuantas manzanas del municipio de Apodaca (19006), donde se muestra la población, el número de viviendas habitadas, el Área Efectiva, la Precipitación Neta Anual Mínima, la Máxima y la Media y por último, el Volumen Captado.

Los valores de la precipitación presentados en dicha tabla se obtuvieron mediante el análisis espacial de la precipitación por manzana. Para observar los resultados completos ver el apartado del Anexo 3, en el archivo digital.

Debido a que presentar los datos por manzana implica tener una base de datos extensa, se realizó un análisis para presentarlos de manera global por municipio, donde se anexó un análisis de la demanda de agua potable que requiere la población del municipio para los años 2010, 2015, 2020, 2025 y 2030; esto con base en las proyecciones realizadas por el Consejo Nacional de la Población (CONAPO, 2014), en el que se basan los datos históricos estadísticos del Censo de Población y Vivienda anteriores al año 2010.

Tabla 6 Resumen de volumen captado por manzanas del municipio de Apodaca (19006)

Municipio	Manzana	Población	Viviendas	Viviendas Habitadas.	Viviendas c/Agua	Área efectiva m²	PNA MIN mm	PNA MAX mm	PNA MEAN mm	Volumen Captado m³

La finalidad de elaborar este análisis que realizar una comparación de cuál sería el beneficio de implementar los sistemas de captación de lluvia contrastándolos con la oferta obtenida. La Demanda de Agua Potable se obtuvo por metro cúbico anual, de manera general, con las proyecciones de la población y en particular, con el registro de la población que habita en las viviendas sin agua. El criterio para determinar el volumen de agua que se requiere, resultó al multiplicar el número de la población por el de una dotación promedio de 300 litros, por habitante, por día, con la cual se realizan proyectos de urbanización en la zona.

Otro resultado obtenido de analizar las variables mencionadas es un volumen promedio por cada metro cuadrado de captación que se tendría por cada municipio, de acuerdo con el promedio de Precipitación Neta Anual presente en la región. Con dicho dato se puede inferir cuál sería el costo beneficio por metro cuadrado de área de captación. Esto se representa en la Tabla 7 se muestra la oferta de agua que tendrían los sistemas de captación de agua de lluvia por municipio, indicando el área de captación y la precipitación neta anual promedio. Además muestra el análisis de la demanda de agua potable en las viviendas que no cuentan con el servicio de agua entubada, para determinar si se podría cubrir la demanda que corresponde a dichas viviendas.

Tabla 7 Resumen global de oferta que tendrían los sistemas de captación de agua por municipio de la Zona Metropolitana de Monterrey.

Contrastando los datos presentados se pueden realizar varios comentarios: primero, si se observa de manera global la oferta producida por los sistemas de captación y la demanda que se tiene de la población que no cuenta con el servicio de agua entubada en su hogar, en toda la Zona Metropolitana de Monterrey, se puede inferir que los sistemas de captación de lluvia, en conjunto, cubrirían tranquilamente la demanda de dicha población, considerando como un sistema en conjunto, ya que al realizar el análisis por manzana se observó que no en todas las manzanas se satisface la oferta total propia de la manzana. Esto se debe a que tanto el número de habitantes como el número de viviendas varían, dependiendo de la extensión de la manzana y, de igual manera, considerando que en algunas manzanas se encuentran centros religiosos y áreas comerciales. Por esto se realizó un plan donde se pudiera gestionar este recurso; añadiendo que se tendrían importantes beneficios.

Otro dato importante que conocer el volumen de agua que se puede captar por metro cuadrado de superficie de captación, que nos indicó un factor útil para el cálculo de la extensión de la superficie de captación necesaria para cubrir, en específico, una demanda en particular. Por ejemplo, en zonas industriales cuentan con grandes extensiones de terreno que serían de gran utilidad para la misma empresa; o viceversa determinar el volumen de agua que se puede captar con una superficie específica de captación.

4.3 DISEÑO DE UNSISTEMA DE CAPTACION DE AGUA DE LLUVIA.

Los resultados obtenidos hasta este punto son preliminares al diseño definitivo, que se implementaría en el Laboratorio de Hidráulica de la Facultad de Ingeniería Civil de la UANL; es decir, sólo se mencionaron dimensiones necesarias para los componentes del sistema de captación de agua de lluvia. El diseño definitivo se planteará como un antecedente para una investigación a futuro, donde se evalúe la eficiencia del sistema de captación de lluvia.

Tomando en cuenta las consideraciones descritas en el método sobre el coeficiente de escurrimiento el área de captación y los componentes a dimensionar, se obtuvieron los siguientes resultados:

Un volumen del Interceptor de las primeras lluvias de 0.75 metros cúbicos, que equivalen a retener 750 litros, en promedio, cuando inicie la precipitación, después de largos periodos de sequía. En periodos húmedos, con el primer día de lluvia es suficiente. Este volumen se dividirá entre las seis bajadas pluviales, por lo que resulta adecuar contenedores para una capacidad mínima de 125 litros. Dichos tanque se adecuará para retener las primeras lluvias y el resto mandarlo a la cisterna de almacenamiento.

La cisterna de almacenamiento se dimensionó con base en la precipitación neta media presente en el municipio donde se ubica el departamento. Se trató de almacenar la mayor parte del agua de lluvia. El volumen calculado requerido para captar toda la lluvia en la cisterna o tanque de almacenamiento es de 120 metros cúbicos, restando los 80 metros cúbicos de la capacidad de la cisterna propia del

laboratorio; por lo que, para tener un diseño óptimo se necesita plantear un modelo en el que se contemple la variación de la precipitación anual y el consumo de agua para los baños y el jardín; ya que es reutilizada el agua que se almacena en la cisterna del laboratorio y actualmente se utiliza para el funcionamiento de los diversos dispositivos, pues lo que corresponde a los sanitarios y jardín se abastece de la red de agua que abastece al Instituto de Ingeniería Civil de UANL.

La finalidad de implantar un sistema de captación de agua de lluvia es hacer al laboratorio un edificio sustentable, realizando un sistema de abastecimiento mixto, en que se abastezca primordialmente de agua de lluvia y, en casos extremos, de la red de agua potable.

CONCLUSIONES Y RECOMENDACIONES.

Los sistemas de captación de agua de lluvia representan un método alternativo para abastecer de manera total o parcial el suministro de agua en una edificación ya sea casa, edificio, escuela o industria; y representan una opción tecnológica viable económica, ecológica y cultural. Debido al bajo nivel de complejidad, los datos son extrapolables y fácilmente adaptables a diversas condiciones ecológicas, donde se presente una precipitación mayor que 200 mm anuales.

El propósito fundamental de esta investigación es el de empezar a generar una cultura en la que se puede tener un beneficio mutuo al poner en práctica estos hábitos y poder disminuir los impactos que se tienen actualmente en las fuentes de abastecimiento, en las grandes ciudades del país

Actualmente en la ciudad de México existe el proyecto “Isla Urbana” que ha tenido una gran aceptación en la capital y la zona centro y sur del país, que consiste en equipar a comunidades rurales y viviendas dentro de la ciudad de México con sistemas de captación de agua de lluvia para consumo humano.

En cuanto a la Zona Metropolitana de Monterrey, no existe algún registro en el que se esté implementando un sistema de captación de agua de lluvia en

escala pequeña, por lo que es importante empezar a generar un registro de la factibilidad de implementar los sistemas de captación de agua de lluvia.

Dicho esto y al realizar el análisis de los resultados obtenidos de esta investigación, en un nivel general, se puede concluir que el impacto que tendría la implementación de sistemas de captación de agua de lluvia en esta zona del país es mínimo, comparado con los datos que se reportan en la zona centro y sur del país, esto si se realiza a pequeña escala; pero si se implementa en el nivel de comunidad, colonia o fraccionamiento, se tendría un impacto mayor, ya que el agua que se captaría en todos los techos de una comunidad se puede juntar y almacenar en una cisterna comunitaria, que serviría como fuente para abastecer los parques y jardines de esa comunidad, incluso si se realiza una planeación adecuada de este recurso, se puede abastecer de agua potable a las comunidades que se encuentran dentro de la zona metropolitana, que carecen del servicio de agua entubada en su hogar.

Por tal razón, es importante poner interés en la gestión de este recurso hídrico, ya que trae implícitamente otros beneficios importantes en una ciudad, como el del control de las inundaciones en temporadas de lluvia, evitando así las complicaciones que traen las inundaciones en las vialidades de la ciudad.

Cabe mencionar que el sistema de captación puede ser muy sencillo o muy complejo dependiendo del uso que se le va a dar al agua captada, ya que para esto interviene la calidad del agua que se capta y la calidad de agua que se requiere para realizar las actividades donde intervenga el uso del agua captada.

Esto implicaría una modificación al tren de procesos para mejorar la calidad inicial que se tenga; es decir, que si el uso principal sería para el riego y el abastecimiento de los dispositivos sanitarios, sólo requiere tener una retención de solidos tales como las hojas de los árboles o alguna otra basura que se acumule en la superficie de captación; es decir, que no requiere de una filtración profunda que le dé al agua o un nivel de purificación de acuerdo con los límites marcados por la norma oficial mexicana NOM-SSA1-127-1994, donde se indica el nivel permisible de compuestos físicos, químicos y bacteriológicos del agua para el consumo humano; por lo tanto, es recomendable realizar un análisis de agua previo en la zona donde se implementará el sistema para de esa manera verificar que el agua cumpla con las propiedades necesarias para su uso adecuado y, de no ser así, implementar además un sistema de potabilización.

RESUMEN AUTOBIOGRÁFICO

Juan Carlos Salinas López
Candidato para el grado de
Maestro en Ciencias con Orientación en Ingeniería Ambiental

Tesis:
EVALUACIÓN DE UN SISTEMA DE CAPTACIÓN DE AGUA DE LLUVIA EN LA ZONA METROPOLITANA DE MONTERREY, PARA SU APROVECHAMIENTO COMO RECURSO ALTERNATIVO.

Campo de Estudio:

Ambiental

Biografía:

Nacido en el Distrito Federal, el 22 de Mayo de 1989, hijo de Mario Salinas Soria y María Mercedes López Llanos.

Educación:

Ingeniero Civil.
Facultad de Ingeniería Civil. Universidad Autónoma de Nuevo León
Enero 2008 – Diciembre 2012.

Experiencia Profesional:

Técnico – Investigador del Departamento de Hidráulica
Instituto de Ingeniería Civil.
Jefe directo: M.C. Ricardo Alberto Cavazos González.
Octubre de 2012 a la fecha.

Contacto:
Correo electrónico: *carlos.salinaslpz@live.com.mx*

ANEXO 3

Resumen de Volumen Captado por Manzanas de Municipios de la Zona Metropolitana de Monterrey, Nuevo León

Archivo Digital, debido a la extensión de la información.
